

Individual Team Member Contribution Journal

Module 2 Lab Exercise - ITAI 1371

Pablo Lara

For this Module 2 lab, my individual contribution was completing and reviewing the Google Colab notebook activities step by step. I opened the provided Module_02_Lab_Exercise.ipynb file in Google Colab, ran the required cells, and checked the outputs to make sure the notebook worked correctly.

I worked through the setup section by importing the required Python libraries, including pandas, NumPy, matplotlib, and scikit-learn. I then loaded the Iris dataset and reviewed the dataset shape, feature names, target classes, and DataFrame structure. I also examined the first five rows of the dataset and confirmed that the data contained 150 samples, 4 features, and 3 classes.

For the visualization portion, I ran the scatter plot code comparing sepal length and sepal width. I interpreted the graph and observed that setosa was more clearly separated from the other species, while versicolor and virginica overlapped more. I also reviewed the basic statistics for each species and the sample counts.

I completed the NumPy task by calculating the mean and standard deviation of sepal length. The mean was about 5.84 cm and the standard deviation was about 0.83 cm. I also completed the matplotlib task by creating a bar chart showing that each species had 50 samples.

I completed the analysis and reflection section by documenting the number of samples, features, and classes, along with observations and questions based on the visualizations and results. I also used the Run all feature in Google Colab to verify that the notebook executed successfully from beginning to end.

This project was my first time working with Google Colab and a Jupyter-style notebook. My main contribution was completing the notebook tasks, checking the outputs, and documenting what I learned from the dataset and the tools used in the lab.
